

# Running IFS on Microsoft Azure

Cathal O'Brien

Cathal.Obrien@ecmwf.int

# Background

- This study wanted to evaluate objectively the pros and cons of HPC on the cloud
- Hoped to develop platform agnostic infrastructure to evaluate other cloud providers in the future
- constraints:
  - Just looking at Azure
  - Just looking at CPU instances, no GPUs
- Hypothesis:
  - Pros: flexible scaling, trying out different hardware
  - Cons: price

# Presentation structure

- Overview of HPC on Azure
- Infrastructure for deploying IFS-capable clusters on the cloud
- Benchmarking results

# Overview of HPC on Azure

# Azure HPC instances

VM	CPU (Cores / Node)	Memory per node (GB)	Interconnect (Gb/s)
HBv2	AMD Rome (120)	456	Infiniband HDR (200)
HBv3	AMD Milan-X (120)	448	Infiniband HDR (200)
HBv4	AMD Genoa-X (176)	704	Infiniband NDR (400)
Atos (Reference)	AMD Rome (128)	256	Infiniband HDR (200)

# Cyclecloud

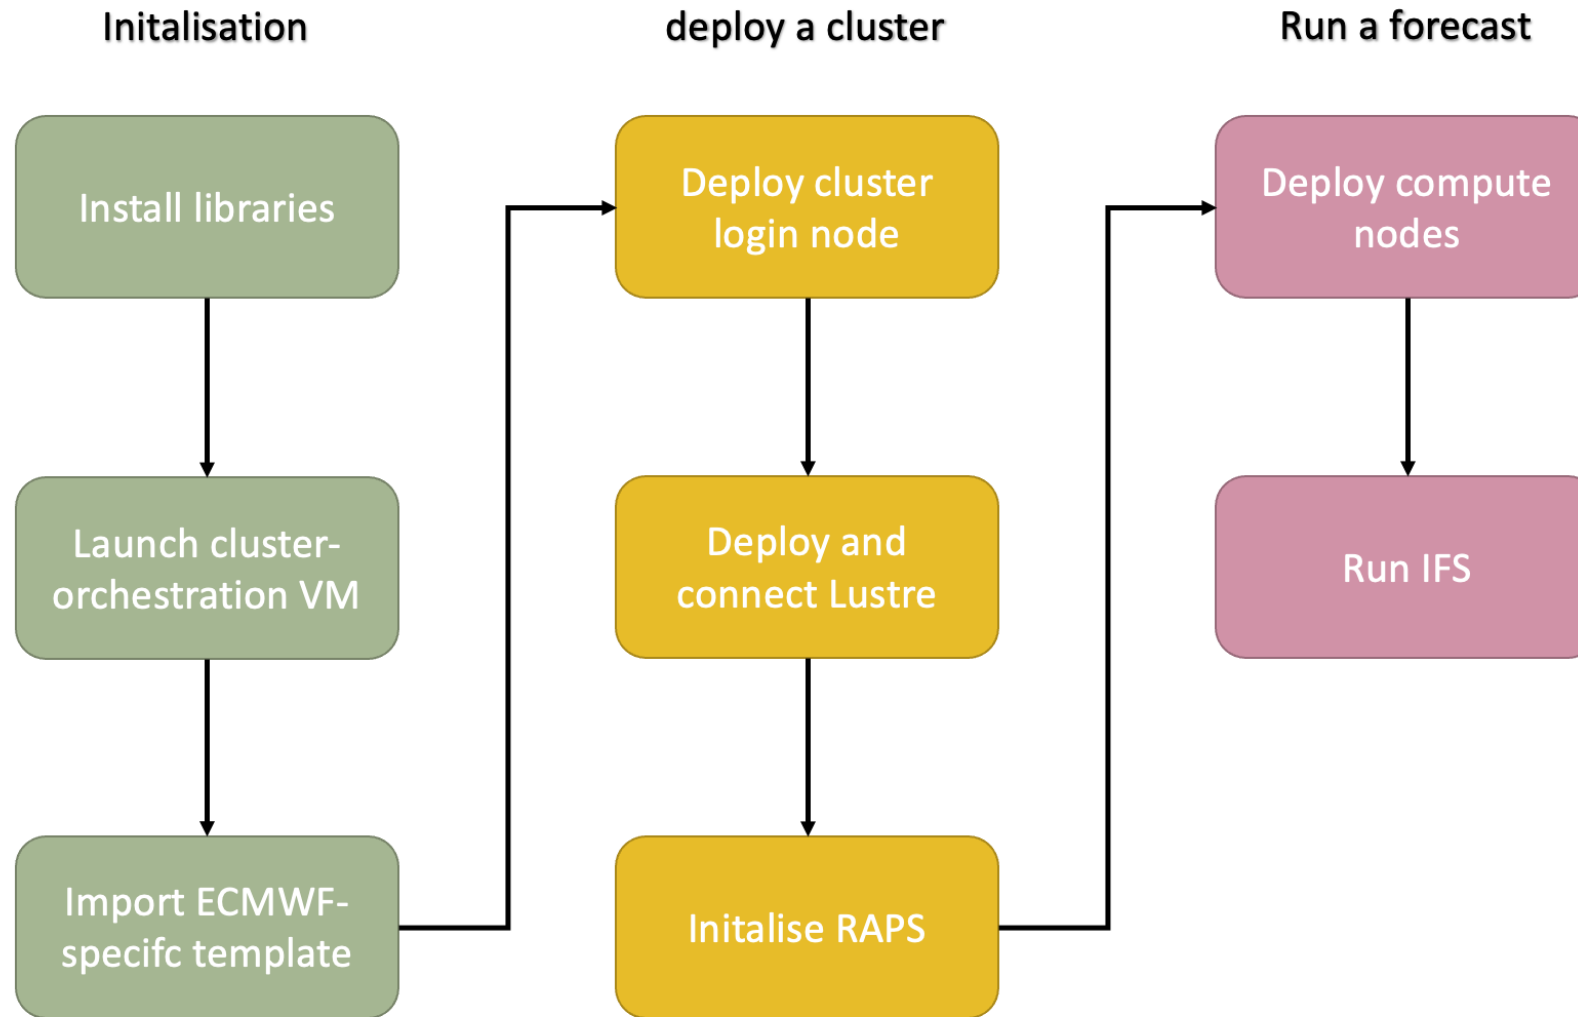

- Software for creating and managing HPC clusters on Azure
- Define cluster templates
  - VM Image, compute queues, etc...
- Persistent login nodes, compute nodes autoscale
- Web portal & command line interface

The screenshot displays the Cyclecloud web portal interface. On the left, a sidebar titled 'Clusters' shows 'hbv3-cluster (17)' selected. The main content area is titled 'hbv3-cluster' and includes a list of actions: Terminate, Edit, Access, Refresh, and Support. The cluster status is 'Started' at 10/10/23 4:19 PM. It shows 1 ready node and 16 preparing nodes, with 1 admin user. The cluster size is 17 instances (2308 cores) at \$0.39 per hour. Usage is 1.5k core-hours (~\$15) in the last 24 hours. There are no issues found.

Nodes	Arrays	Activity	Monitoring	Scalesets
View: Template <input type="button" value="Refresh"/> Actions <input type="text" value="Search"/>				
Template	Nodes	Cores	Status	Last Status Message
hbv4	16	2304	<span style="background-color: #0070c0; color: white;">Progressing</span>	Configuring software
scheduler	1	4	<span style="background-color: #70ad47; color: white;">Ready</span>	....

# Infrastructure for deploying IFS-capable clusters on the cloud

# Cluster creation pipeline

# Initialisation

- Create Virtual Machine Image
  - Based on an existing Azure HPC Image loaded with OFED drivers etc
  - Install compilers and MPI libraries
  - Prebuild IFS build for all relevant stacks
- Provide user login details and billing info
- Deploy Cyclecloud using Terraform

# Deploy a cluster

- Cluster based on custom template
  - Slurm scheduler
  - Spot partitions for HBv2, HBv3 & HBv4
  - on-demand partitions for longer jobs
- Launches the cluster and does some further configuration which couldn't go into the Image
  - Setup SSH keys
  - Configure git
  - Clone repos

```
[[nodearray hbv3]]  
Extends = nodearraybase  
MachineType = Standard_HB120-96rs_v3  
ImageID = $ImageID  
MaxCount = $MaxNodes  
Azure.MaxScalesetSize = $HPCMaxScalesetSize  
AdditionalClusterInitSpecs = $HPCClusterInitSpecs  
Interruptible = true  
MaxPrice = $SpotMaxPrice
```

```
[[[configuration]]]  
slurm.default_partition = true  
slurm.hpc = true  
slurm.partition = hbv3  
slurm.use_pcpu = false
```

Cyclecloud template block defining a compute partition

## Deploying Lustre on the cloud

Throughput (MB/s/TiB)	Block size (TiB)	Max capacity (TiB)	Price (\$/GiB/month)	Price (\$/Block/hour)
40	48	768	0.084	5.65
125	16	128	0.145	3.25
250	8	128	0.21	2.36
500	4	128	0.341	1.91

- Lustre can be linked to blob storage to populate it lazily with input data
- Script created to deploy Lustre in ~10 mins
- Load inputs into lustre before job starts
  - 700GB, ~10k files, ~15 mins
- Lustre on the cloud can – and should – be spun up on-demand
  
- Nice side benefit: getting input data on cluster in ~25 mins via Lustre vs hours using scp!
  
- IOR benchmarking from Microsoft available [here](#)

# Run a forecast

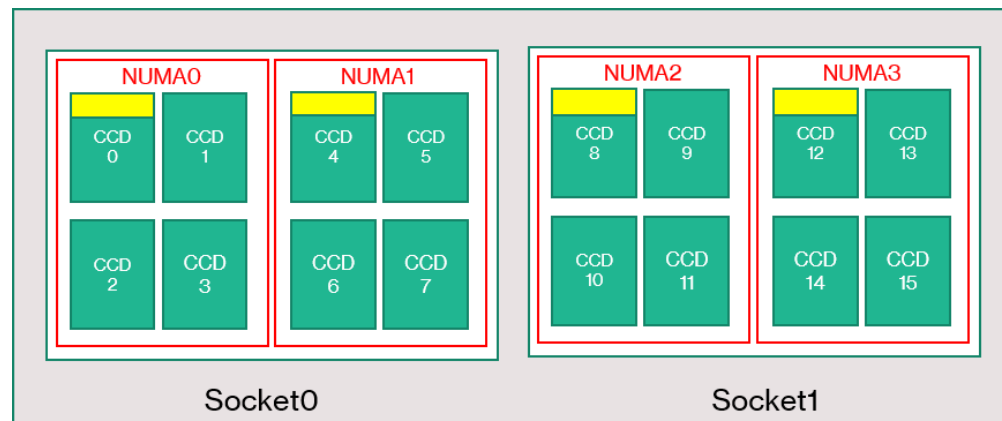

- Start nodes
  - ~2 mins to find nodes (asking for 100 nodes will take longer)
  - ~4 mins to configure software
- We had an issue with ~10% of nodes being unhealthy
  - Instead of using Slurm we created a script to start the nodes
  - Allocates additional nodes, then runs a health-check and returns a subset of nodes which passes these tests and deallocates the rest
  - This specific issue is fixed now
- Once nodes are started, run jobs with Slurm as usual
  - Works OK but Slurm integration could certainly be better

```
[hpc_admin@hbv3-cluster-scheduler ~]$ sinfo
PARTITION AVAIL  TIMELIMIT  NODES  STATE NODELIST
hbv2       up    infinite   99   idle~ hbv3-cluster-hbv2-[1-99]
hbv3*      up    infinite   99   idle~ hbv3-cluster-hbv3-[1-99]
hbv4       up    infinite   38   idle~ hbv3-cluster-hbv4-[1-29,32-40]
hbv4       up    infinite    2   down* hbv3-cluster-hbv4-[30-31]
```

# Benchmarking results

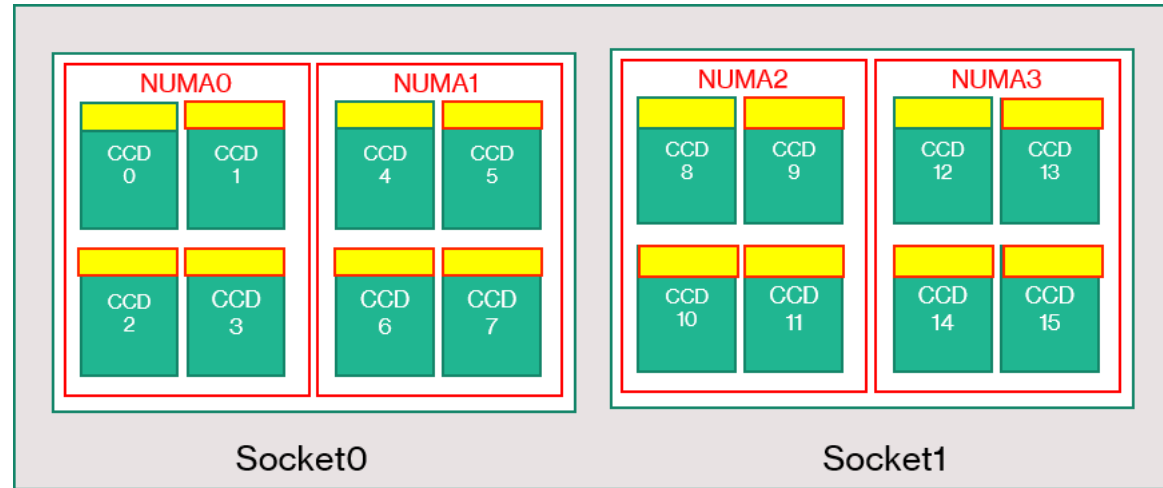

# Task pinning on Azure HBv3

- Pinning locks processes to specific cores on the node and is crucial for achieving good performance
- Otherwise, OS can migrate MPI tasks across the node, decreasing performance
  - Cache invalidation
  - Accessing data in different NUMA domains
- Cloud hypervisor adds an extra difficulty here

# Task pinning on Azure HBv3

Size	vCPU	Processor	Memory (GiB)	Memory bandwidth GB/s
Standard_HB120rs_v3	120	AMD EPYC 7V73X	448	350
Standard_HB120-96rs_v3	96	AMD EPYC 7V73X	448	350
Standard_HB120-64rs_v3	64	AMD EPYC 7V73X	448	350
Standard_HB120-32rs_v3	32	AMD EPYC 7V73X	448	350
Standard_HB120-16rs_v3	16	AMD EPYC 7V73X	448	350

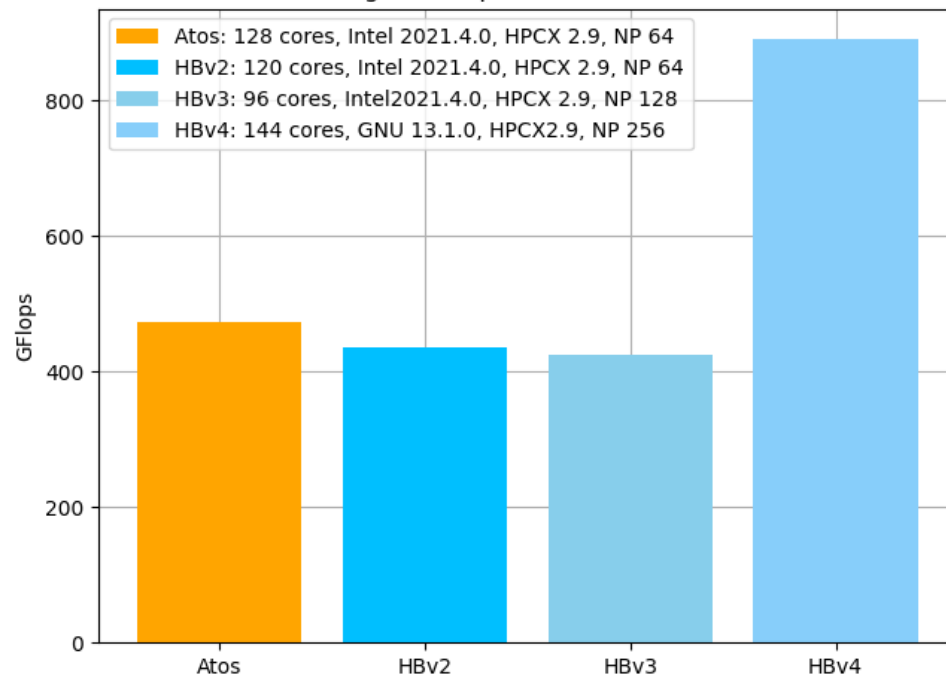

- Further reduces available cores
  - HBv3: 128 => 120 => 96 cores
  - HBv4: 192 => 176 => 144 cores
  - HBv2: 128 => 120 cores (different HV layout)
- Still exclusive use of entire node
- Not present on all cloud providers

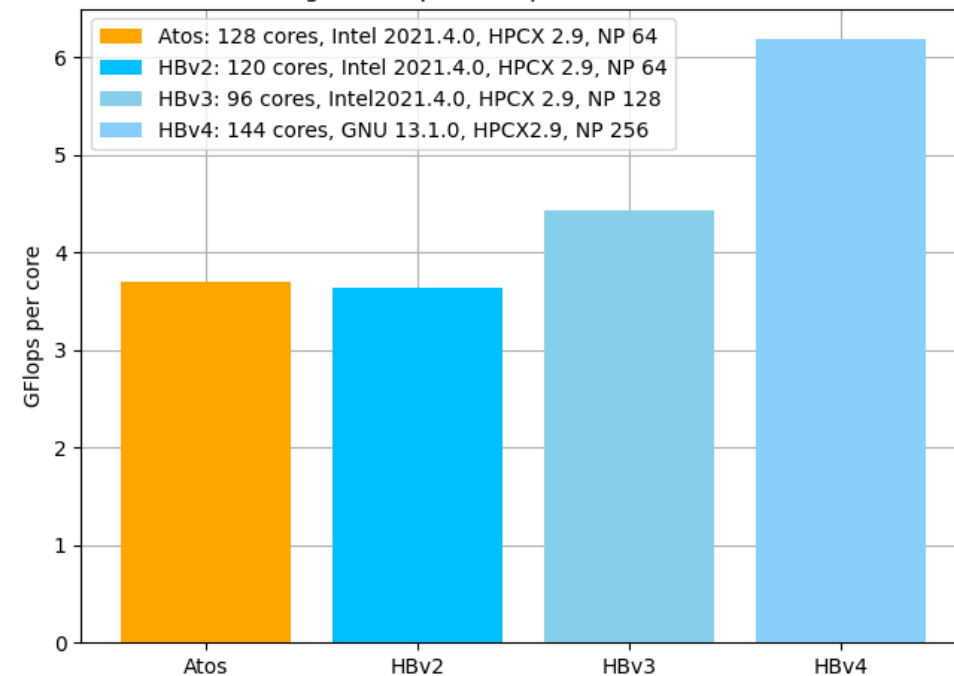

# Cloudsc

- Cloud microphysics scheme extracted from IFS
- Available on [Github](#)
- Hybrid MPI - OpenMP, usually run on a single node for benchmarking
- Compute bound on most architectures
- Higher is better

Cloudsc SP single node performance on Azure and Atos

Cloudsc SP single node per-core performance on Azure and Atos

# ECRad

- Atmospheric radiation scheme
- Available on [Github](#)
- Memory bound on most systems
- Pure OpenMP, runs within a single NUMA domain for First Touch reasons
- Higher is better
- Dashed line = 200GBs of Statically Allocated Huge Pages on Azure

Ecrad strong scaling on Azure

# ECTrans

- Spectral transform
- Hybrid MPI-OpenMP, many nodes
- Available on [Github](#)
  
- Unfortunately when time came to benchmark we had a memory leak when running on Azure

# OSU Benchmark suite

- Above, lower is better
- Below, higher is better
- High latency at small message sizes requires further investigation

OSU latency test on azure

OSU p2p BW test on azure

# IFS – Strong Scaling

IFS 48R1 Strong Scaling

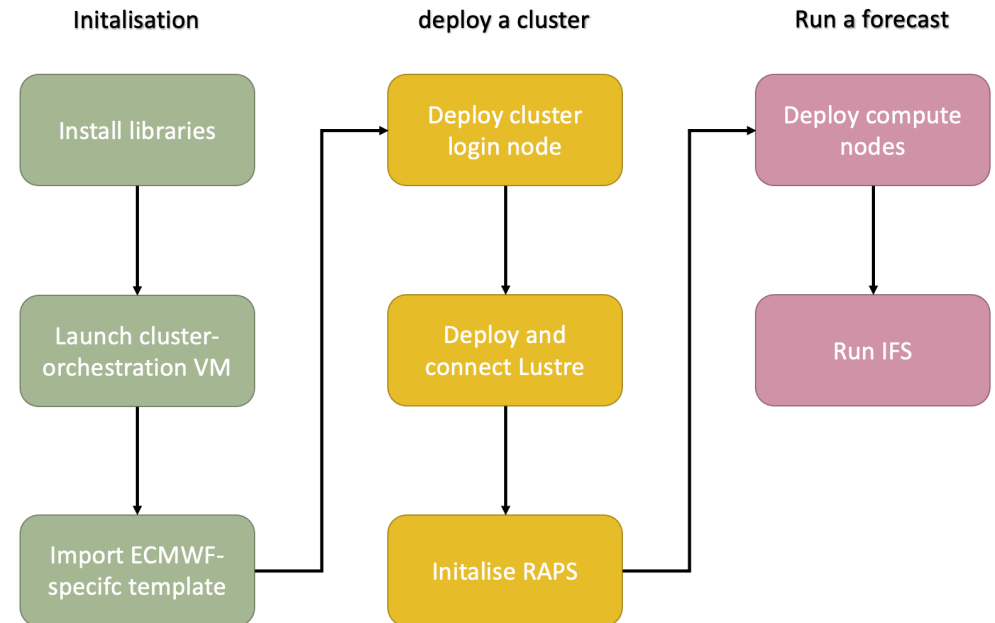

- Caveats:

- IO turned off, no comparison to Atos
- Lacking optimisations like Statically Allocated Huge Pages
- IB for HBv4 was not available

# Conclusion

- Cloud is great for flexibly trying out new hardware
  - Great performance results
  - Quotas and budget limits scaling
- Significant setup work involved
- HPC on the cloud still a young field

# Thanks

- Thanks to Alexandre Jean, Cedric Husianycia & everyone from Microsoft for their support

### Noise in the Clouds: Influence of Network Performance Variability on Application Scalability

Daniele De Sensi, Tiziano De Matteis, Konstantin Taranov, Salvatore Di Girolamo, Tobias Rahn, Torsten Hoefler

Cloud computing represents an appealing opportunity for cost-effective deployment of HPC workloads on the best-fitting hardware. However, although cloud and on-premise HPC systems offer similar computational resources, their network architecture and performance may differ significantly. For example, these systems use fundamentally different network transport and routing protocols, which may introduce network noise that can eventually limit the application scaling. This work analyzes network performance, scalability, and cost of running HPC workloads on cloud systems. First, we consider latency, bandwidth, and collective communication patterns in detailed small-scale measurements, and then we simulate network performance at a larger scale. We validate our approach on four popular cloud providers and three on-premise HPC systems, showing that network (and also OS) noise can significantly impact performance and cost both at small and large scale.
